# Announcements

---

- ❑ Last Homework due Tuesday
- ❑ THURSDAY: last lecture! Final review (Prof. Das)

# Outline for Today's Lecture

---

- ❑ Why Building Secure Hardware?
- ❑ Security Basics
- ❑ Security Exploits in Hardware
- ❑ System Security Protections

# Why is Security Important?

## (to Architects and Compiler Designers)

---

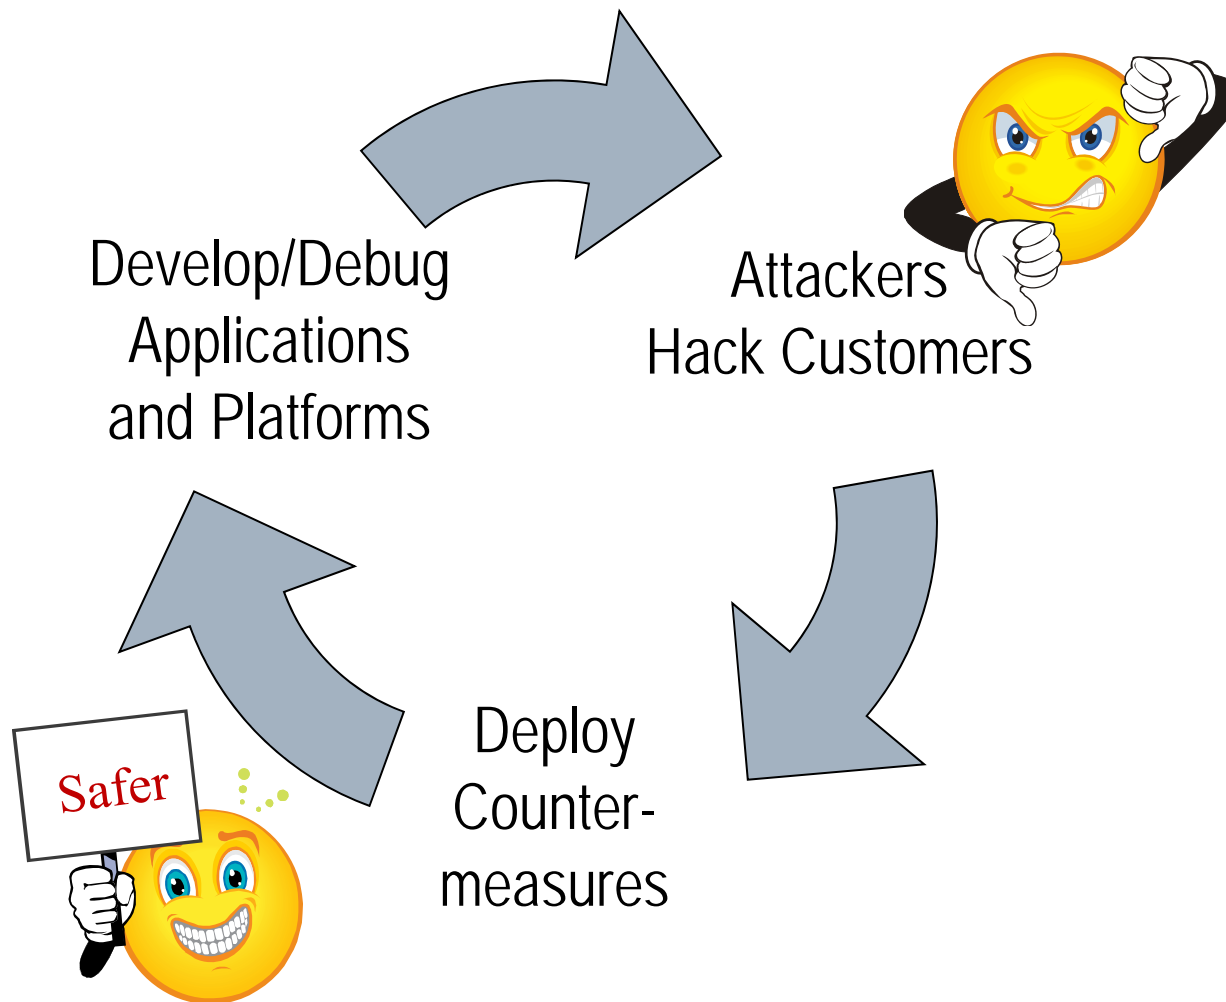

OPPORTUNITY: Hardware and system-level solutions are needed to protect software and intellectual property (IP)

- ❑ Hardware and low-level software support improves speed and quality of cryptography
- ❑ Hardware and system-level software support can most effectively seal up security vulnerabilities

COST: Hardware and system-level software vulnerabilities enable security attacks

# The Security Arms Race

---

# Why Do Attackers Attack?

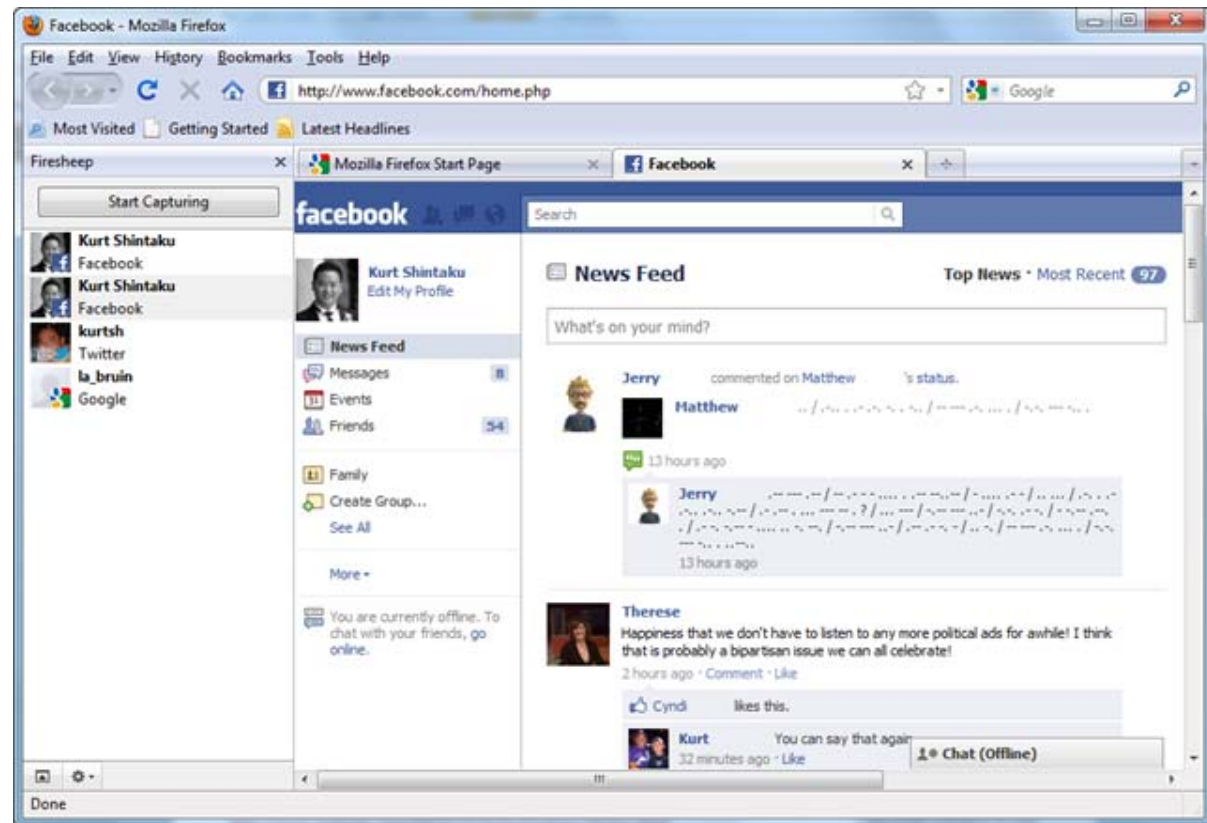

---

- ❑ To gain access to private information, e.g., credit card numbers
- ❑ To punish/embarrass individuals and institutions, e.g., Sony
- ❑ To gain control of machines, e.g., BotNets

# Why Do Attackers Attack?(cont)

- ❑ To educate and advocate, e.g., FireSheep
- ❑ To earn reputation in the attacker community, e.g., hackers vs. script kiddies
- ❑ etc...

# The Ultimate Goal of the Designer

---

- ❑ Win the bear race...

# Flood of Malware

## Why we are losing the battle?

"Hardware Malware Detectors" Demme, et al.

# Recent developments: hw-based attacks

---

- ❑ 2008: Kris Kaspersky announced the discovery of an OS-independent remote code execution exploit based on an Intel CPU bug (not disclosed)
- ❑ 2008: UIUC researcher Sam King demonstrate that 1400 additional gates added to a Leon SPARC processor creates an effective Linux backdoor
- ❑ 2008: Princeton researcher Ed Felten demonstrates that disk encryption keys can be extraction after system shutdown from frozen DRAM chips
- ❑ 2010: Christopher Tarnovsky announced a successful hardware exploit of an Infineon TPM chip
- ❑ 2011: Sturton/Hicks develop non-stealthy malicious circuits, provide plausible deniability to rogue designers
- ❑ 2014: Rowhammer bug demonstrated, able to flip DRAM bits in adjacent rows even without access permission

# What is Authenticated Communication?

---

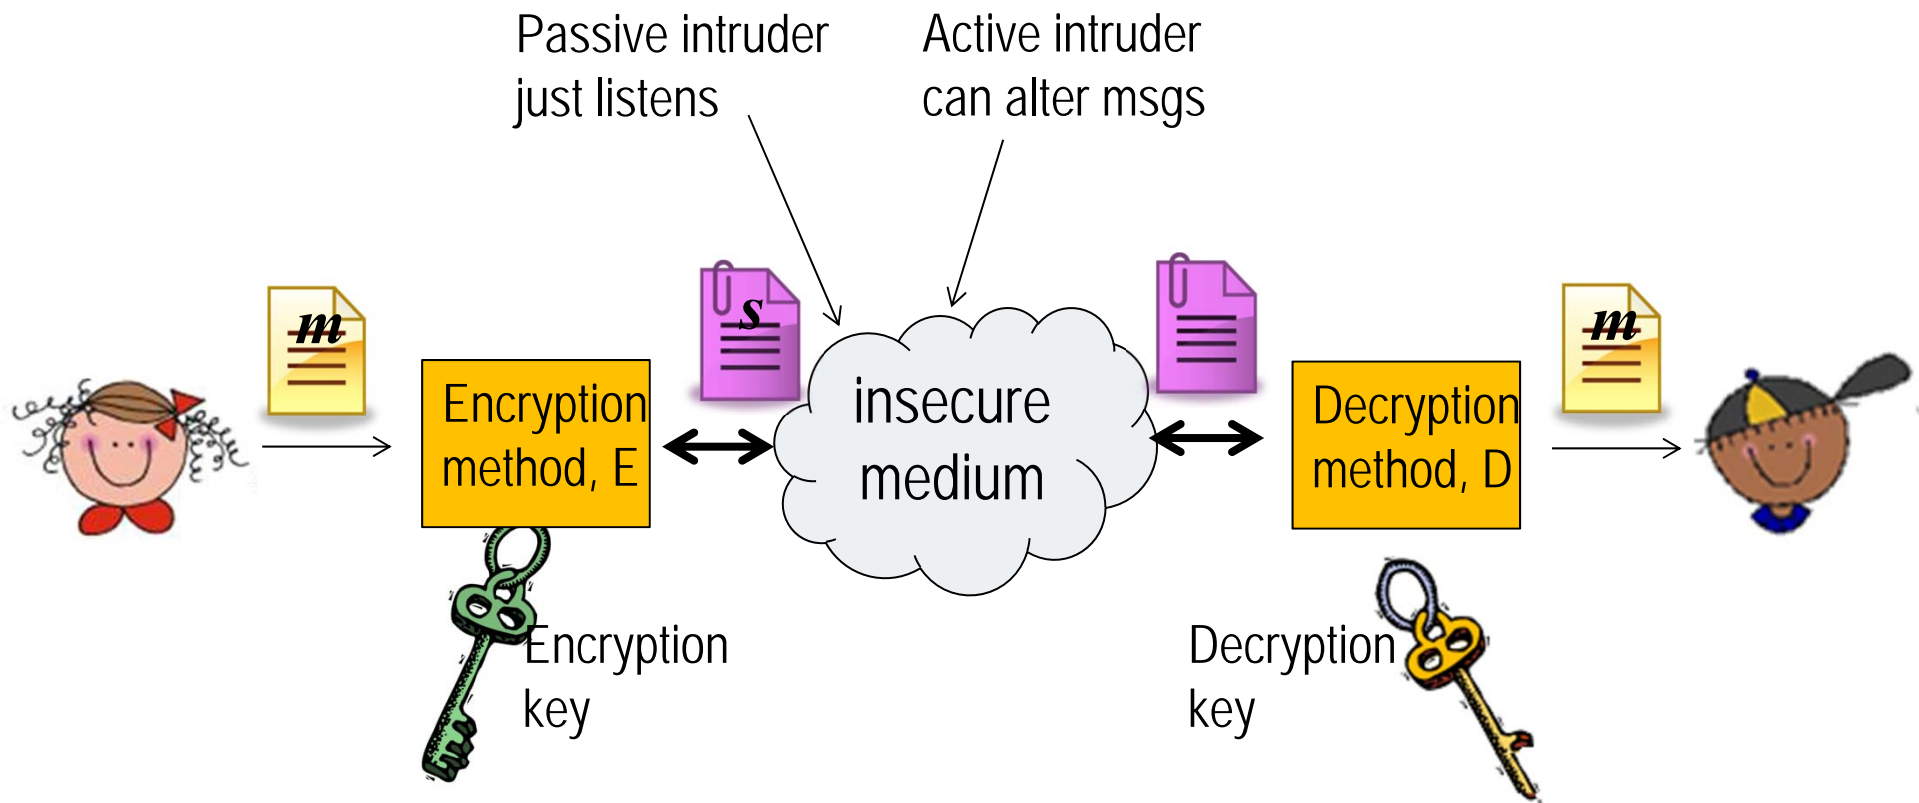

How do we enable authenticated communication?

---

# Terminology

---

# Symmetric Key Cryptography

---

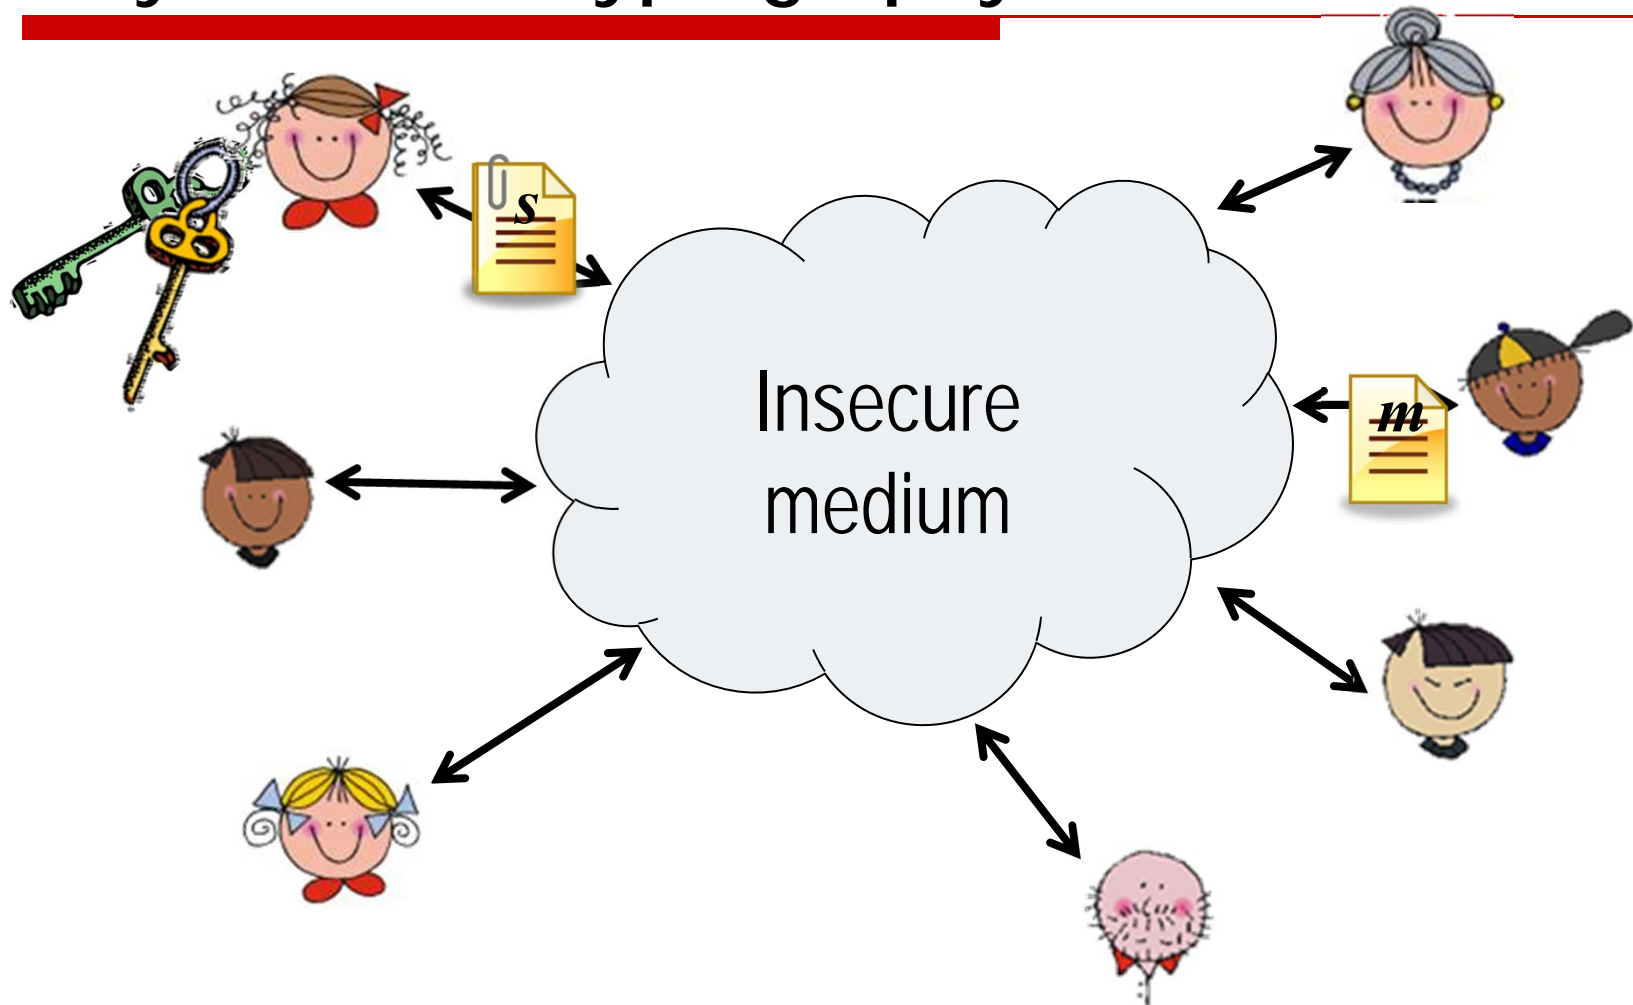

- ❑ Sender and receiver share the same private key
- ❑ Key has to be exchanged by some other mean
- ❑ Anyone who knows the private key can listen in
- ❑ Has to be REVERSIBLE
- ❑ Often called a "private-key cipher"
- ❑ Examples: AES, DES, Blowfish

# Asymmetric Cryptography

---

# Asymmetric Key Cryptography

---

- ❑ Sender has the receiver's public key, receiver has the private key
- ❑ Anyone can encrypt a message with the public key, only the holder of the private key can decrypt the message
  - Allows sharing of private information with no initial shared secret
- ❑ The reverse path also works: everyone can decrypt a message that was encrypted by the holder of the private key
- ❑ Often called a "public-key cipher"
- ❑ Examples: RSA, Diffie-Hellman

# RSA Authentication

---

- ❑ Client sends a unique message to server
- ❑ Server encrypts unique message with private key
- ❑ Client decrypts the message with public key and verifies it is the same
- ❑ **Authentication:** only server could return private-key encrypted unique message

# Attack on RSA

Bertacco, et al.

RSA Server: Sparc v8@40Mhz

OpenSSL  
debian  
Leon3  
VIRTEX-III  
PRO

# Faulty RSA Authentication

*Correct Authentication:*

- Server challenge:  
 $s = m^d \bmod n$
- Client verifies:  
 $m = s^e \bmod n$

*Faulty Server:*

$$\hat{s} \neq m^d \bmod n$$

# Symmetric vs. Asymmetric Ciphers

---

## ❑ Symmetric Ciphers

- Fast to compute
- Require prior shared knowledge to establish private communication

## ❑ Asymmetric Ciphers

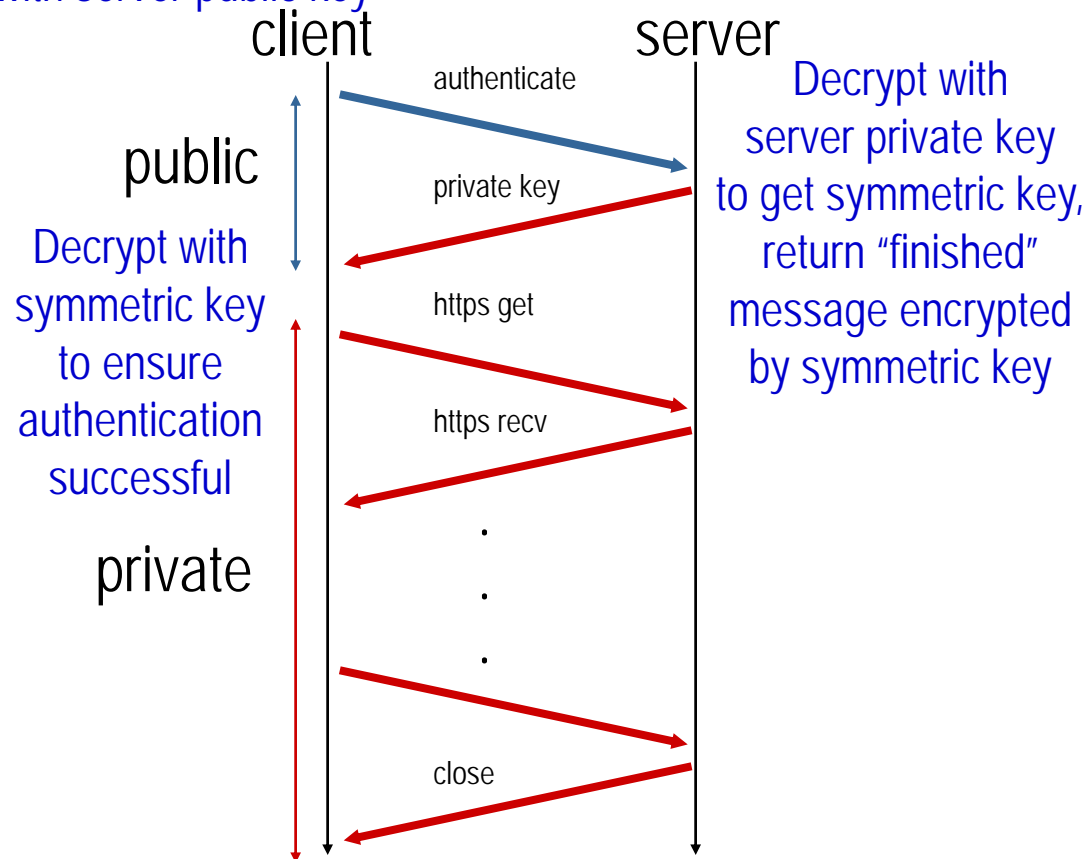

- Orders of magnitude slower to compute
- No shared secrets required to establish private communication

## ❑ Individual benefits create a need for both types of cryptography

# Secure Sockets Layer (SSL) Overview

---

Encrypt client symmetric key (random number) with server public key

# Verifying Integrity: Hash Functions

---

Arbitrary-length  
message  $m$

Fixed-length  
message digest  $y$

Cryptographic hash  
Function,  $h$

*0xdeadbeefbaadf00d*

- ❑ Goal: provide a (nearly) unique “fingerprint” of the message
- ❑ Hash function for  $L$ -bit hash must demonstrate three properties:
  1. Fast to compute  $y$  from  $m$ .
  2. One-way: given  $y = h(m)$ , can't find  $m'$  satisfying  $h(m') = y$  without  $O(2^L)$  search
  3. *Strongly* collision-free: For  $m_1 \neq m_2$ , we find  $h(m_1) = h(m_2)$  with probability  $1/2^L$
- ❑ Widely useful tool, e.g., Has this web page changed?
- ❑ Examples: MD5 (cryptographically broken), SHA-1, SHA-2

# Hash Application: Password Storage

---

- ❑ Never store passwords as plain text
  - If your machine is compromised, so too are all the user passwords
  - E.g., Gawker.com attack in 2010
- ❑ Why protect passwords on a compromised machine?
- ❑ Instead, store a cryptographic hash of the password
  - Even with a compromised password file, the passwords are still unknown
  - Use “salt” to eliminate the use of “rainbow tables”

# Security Vulnerabilities are Everywhere

- ❑ Most often born out of software bugs
- ❑ NIST estimates that S/W bugs cost U.S. \$60B/year
- ❑ Many of these errors create security vulnerabilities

# Buffer Overflow Attack

- ❑ Buffer overflows constitute a large class of security vulnerabilities
- ❑ Goal: inject code into an unsuspecting machine, and redirect control

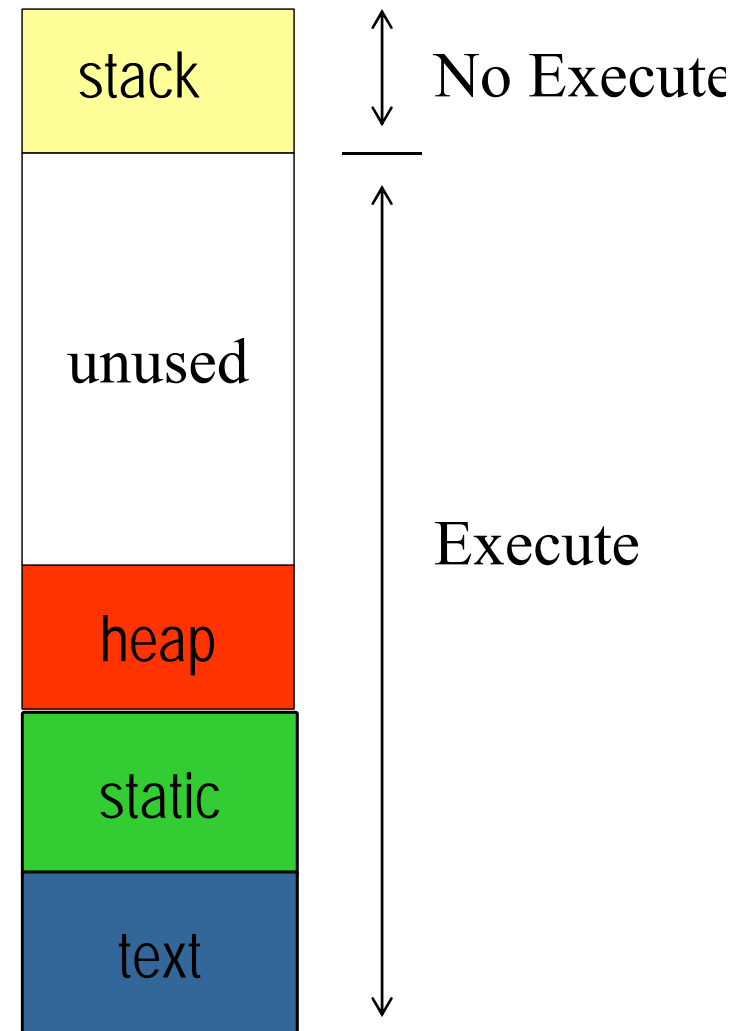

```
void foo()  
{  
    int local_variables;  
    int buffer[256];  
    ...  
    buffer = read_input();  
    ...  
    return;  
}
```

If read\_input() reads >256 ints

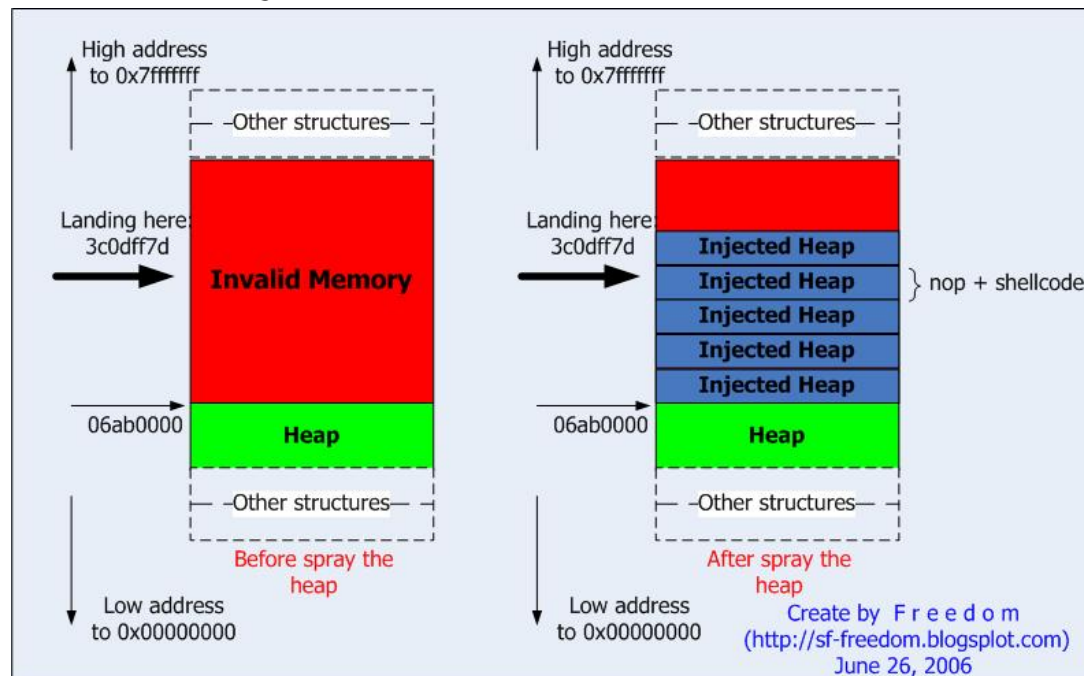

# No-Execute (NX) Stacks

- ❑ Eliminate stack code injection by preventing code execution on stack
- ❑ Can be a problem for some safe programs, e.g., JITs
- ❑ NX bit in newer x86 PTEs indicates no-execute permission for pages

# Escalate: No code allowed on stack

- ❑ Use a *heap-spray attack*

- ❑ Inject executable data into heap, then perform random stack smash
  - Example, generate many strings in Javascript that are also real code
- ❑ Generous heap sprays will likely be found by stack smash attack

# Address Space Layout Randomization (ASLR)

- ❑ At load time, insert random-sized padding before all code, data, stack sections of the program
- ❑ Successfully implementing a buffer overflow code injection requires guessing the padding geometry ***on the first try***
- ❑ Implemented in recent Windows, Linux and MacOS kernels

# Escalate: No new code allowed at all

---

- ❑ Use **return-oriented programming** to attack...
- "RET" instruction transfers control to address on top of stack.
- Return-oriented programming introduces no new instructions, just carefully craft injected stack returns to link existed function tails
- New program is formed from sequence of selected function tails composed from existing code

# Stack Canaries with StackGuard

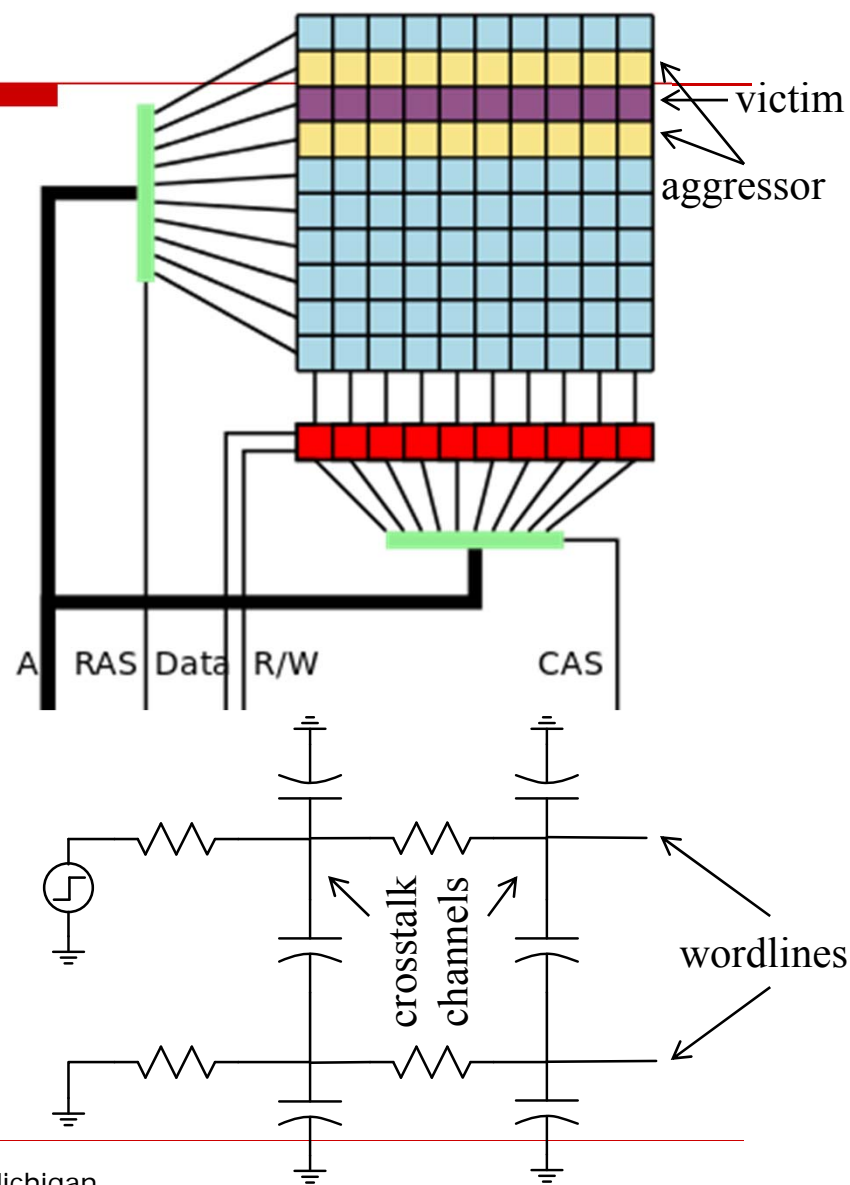

---

- ❑ Implemented in compiler (GCC), runtime check of stack integrity
- ❑ Embed “canaries” in stack frame before the return address, in function prologue, verify their integrity in function epilogue
- ◆ Canary is a per-instance random value that attacker must guess ***on the first try*** for a successful attack
- ◆ About 10% overhead for typical programs
- ◆ Can be thwarted with overflow attacks on function pointers

# Row Hammer Attack

- ❑ Attack flips bits in victim DRAM row, without permission to access
  - Result of wordline crosstalk
  - Creates small pulses on adjacent wordlines, increases bitcell leakage
  - Hammer enough times (~400k) in one refresh cycle (~64ms) and bits will flip in victim row
- ❑ Typical protection requires doubling the refresh rate
- ❑ Why doesn't this happen all the time?

# Cold-Boot Attacks

---

- ❑ Cold-boot attacks steal encryption keys
  - Super-cool DRAM, rip it from running machine
  - Analyze it in a second machine without security
  - Circa 2007
- ❑ Many modern DDR3+ interfaces utilize memory scrambling
  - Data to DRAM is encrypted with per-boot key
  - Non-chained cipher, only 48 key expansions
- ❑ Recently, Michigan PhD students cold-boot attacked a DDR3 interface
  - Used known plaintext to identify key expansions
  - Located TrueCrypt AES keytable, regen'ed key

# Things to remember

---

- ❑ Don't make yourself an easy security target!
  - Change passwords
  - Use different passwords for different sites
- ❑ Don't invent your own cryptographic algorithm, unless that is your only career goal.
- ❑ Think of security from the start as you design new systems, software or hardware
- ❑ This is just the beginning -- security is a growing and rewarding challenge

**See you all at the final!**
